Topics

Given a string consisting of letters, '*a*', '*b*' and '*c*', we can perform the following operation:

- Take any two adjacent distinct characters and replace them with the third character.

For example, if '*a*' and '*c*' are adjacent, they can be replaced by '*b*'.

Find the smallest string which we can obtain by applying this operation repeatedly.

Input Format

The first line contains the number of test cases *T*. *T* test cases follow. Each test case contains the string you start with.

Constraints

- $1 \leq T \leq 100$
- The string will have at most 100 characters.

Output Format

Output *T* lines, one for each test case, containing the smallest length of the resultant string after applying the operations optimally.

Sample Input

```
3
cab
bcab
cccc
```

Sample Output

```
2
1
5
```

Explanation

For the first case, you can either get *cab* → *cc* or *cab* → *bb*, resulting in a string of length 2.

For the second case, one optimal solution is: *bcab* → *aab* → *ac* → *b*. No more operations can be applied and the resultant string has length 1.

For the third case, no operations can be performed. So the answer is 5.
